Abstract

The marble provenance of 163 Roman Imperial portraits, stretching approximately over 500 years, has been established with the purpose of obtaining quantitative, diachronic data on the use of sculptural marbles in Roman times. The overall result shows that Göktepe was the most widely used variety (45%) followed at a great distance by the Parian *lychnites* (27.5%), whereas other marbles such as Carrara or Docimium played a more limited role. The use of Göktepe for high quality portraits, already known in Trajanic times, became widespread from the early 2nd century AD and apparently reached its apogee under the Severans continuing to be widely used till late antiquity. The significance of these results on the technical and stylistic trends that were popular at Rome in Imperial times is briefly discussed.

Keywords

imperial portraits, marble provenance, Göktepe quarries

1. Introduction

Recent work carried out on the sculptural white and black marbles of Göktepe seems to suggest that they were among the most prized varieties used for fine sculpture, particularly during the middle and late Imperial times. Approximately 500 statues, mostly white but also including many black artifacts, have been tested at Rome, Aphrodisias and in many provincial sites in Italy, North Africa, and other regions of the Empire.¹ The results show that Göktepe is the source of approximately 160 sculptures corresponding almost to 1/3 of the total. With only one exception, the black Canephorae that decorated the house of Augustus and are now in the Palatine Antiquarium, all the black marble sculptures tested proved to be Göktepe *bigio morato* or *nero antico*. The white variety, sporadically used already in Julio-Claudian

times, apparently became, from the early 2nd century AD, the most prized marble for manufacturing top-quality portraits and ideal sculptures, largely replacing other marbles such as the Parian *lychnites* that were dominant in earlier periods. The success met by the marbles of Göktepe increased during the mid and late 2nd century AD, apparently reaching its apogee in Severan times but continuing to be widely used till late antiquity. Extensive provenance data have been published and the reader is referred to specific publications for details.²

Obviously this large amount of unexpected results is drawing increasing attention: recent handbooks on Roman marbles acknowledge the existence and role of Göktepe³ and a growing number of research groups is taking into account the possibility of Göktepe provenance by including published quarry data⁴ into their databases.⁵ Despite this, the role and the importance of the site have not yet been fully perceived. Reasons include the novelty of the results and the fact that new provenance data are not easily accommodated within a frame of quarries and provenances that seemed to be well established. In addition, most Göktepe studies have been carried out, up to present, by a single research group lacking the cross-check validation that is much needed for any new scientific achievement. Luckily enough, this problem is being overcome: new groups plan to survey the quarries obtaining and characterizing new quarry samples⁶ while the use of existing data is slowly spreading.

There is, however, a different and more important reason that makes it difficult to understand in detail the role played by Göktepe and other sculptural marbles in Roman times. This is the lack of systematic data that would allow precise estimates of the share of each marble

Table 1. Summary marble provenance of the 163 Imperial portraits tested grouped into eight chronological periods

for different types of sculptures within different archaeological contexts and periods of time. The present work is a preliminary attempt to fill the gap by focusing on the analysis of 163 Imperial portrait sculptures, mostly coming from Rome and stretching over several centuries. The artifact choice was suggested by the known fact that portraiture played a major role in Roman art and the sculptures were generally made using carefully selected marble varieties. This is especially true for portraits of Emperors and other members of the imperial family, that, especially when coming from Rome, were top-quality productions and offer the additional advantage of fairly well-known chronologies.⁷

2. The sampled artifacts

The 163 portraits discussed in this work extend from Julio-Claudian times to late antiquity. Two portraits of Caesar are included, while the latest artifact is a portrait of Valens or perhaps Honorius (Capitoline Museums, inv. 494) dated to the end of the 4th or beginning

of the 5th century AD. For the purpose of chronological analysis the portraits, which span a total time lapse of ca. 500 years, were grouped into eight categories (Table 1). Unfortunately the overall time distribution is not as homogeneous as would be desirable. Some groups, such as those of the Flavian or Trajanic periods, include only a limited number of sculptures. The chronological inhomogeneity may obviously bias the distribution results obtained for the less numerous groups and represents a problem that, it is to be hoped, future work will correct.

The selection includes 30 different emperors and 22 members of the imperial families. Many historical figures are represented just by one or few portraits. In other instances, however, several items could be sampled: up to 13 for Antoninus Pius or 14 for Marcus Aurelius. Most artifacts were analyzed specifically for this work, others were tested in the past for different purposes and two were taken from the literature.⁸ The portraits, whose original locations were in most cases Rome, come from 16 different museums or archeological sites, among which the National Archaeological Museum at Naples

⁷ It is important to note that some of the portraits have been re-worked and therefore their true chronology is earlier than the time of the Emperor that is being portrayed.

⁸ They are the so-called Augustus of Prima Porta now in the Vatican Museums and the togatus statue of Caligula in the Virginia Museum of Fine Arts (inv. 71.20) that are both unquestionably made of Parian *lychnites*.

Fig. 1. Distribution histogram of the 12 different marble varieties identified by testing 163 Roman Imperial portraits

(35), the Roman villa of Chiragan (33), Palazzo Massimo in Rome (28), the Uffizi galleries in Florence (19), the Capitoline Museums in Rome (6) and the Louvre (4) can be recalled.

No sample selection, trying to sort out likely Gök-tepe candidates, was attempted. The obvious reason is that the purpose was to obtain an unbiased selection of sculptures capable of reproducing as closely as possible the actual distribution of the marble. Moreover, sampling imperial portraits is a problematic task that, even when possible, allows only extremely small samples to be obtained. Therefore the very simple strategy adopted was that of sampling whatever became available.

It must be added that presenting in detail all the results goes far beyond the limits of a conference paper. Therefore, only a summary account of the work will be given here. However, the marble distribution results and corresponding histograms that are the most important outcome of the work are drawn taking into account the complete set of analyses.

3. Experimental methods and marble database

The portrait marbles were characterized by isotopic, EPR, grain size and trace metal analyses, the latter focusing on Mn, Sr, and Fe data. The experimental procedures and the methods of data analysis have been repeatedly discussed in the past and the reader is referred to previous publications for details.⁹ Considering that the marbles used for the portraits show a range of different

properties a relatively ample selection of the general marble database had to be used including 12 different marble sites. Many of them are known to produce marbles exhibiting distinctly different properties. For this reason the sites selected as possible provenances correspond to the 20 different marble groups summarized below:

Carrara, Hymettos, Pentelicon, Paros (3 groups), Thasos (2 groups), Altıntaş, Aphrodisias, Afyon, Ephesos (3 groups), Gök-tepe (2 groups), Proconnesos (2 groups), St. Béat (2 groups).

Only purely local varieties or marbles clearly incompatible with the properties of the archaeological samples were neglected. In contrast with this, the quarry selection includes the St. Béat site in the French Pyrenees. This is due to extensive work carried out at Toulouse on sculptures coming from the Roman villa of Chiragan and other locations in the area. Some of these portraits, in fact, particularly the late antique artifacts coming from Chiragan and known as the “dynastic group”¹⁰ proved to be made of local St. Béat marble.

4. Results

4.1. General remarks

The histogram of Figure 1 shows that the portraits tested were manufactured using 12 different marbles. It is worth noting, however, that four varieties alone, that is, Gök-tepe, *Lychnites*, Carrara and Docimium, account for the great majority of sculptures (139 examples, 85.3%). Among them Gök-tepe is by far the most frequent (74

⁹ ATTANASIO *et al.* 2013; PROCHASKA, GRILLO 2010; PROCHASKA 2013.

¹⁰ BALTY, CAZES 2008, 123-140.

Fig. 2.
Multi-method

most used portrait marbles,
using a combination of
isotopic, EPR, strontium
and grain size data

examples, 45.4%) followed at a great distance by Parian *lychnites* (35 samples, 21.5%). On this basis it can be stated that within the whole period of time spanned by the sculptures (ca. 500 years), Göktepe was the marble most commonly used by far. Aside from the four varieties just mentioned, the use of other marbles appears to be sporadic and does not exceed 3%, as demonstrated by five artifacts made of Thasian dolomite, the marble that ranks fifth in the frequency list.

Before proceeding to more detailed analyses, however, it is necessary to consider the question of reliability. Using the quarry selection mentioned in section 3, the rate of success of the method is 75%. This means that 75% of the database samples are re-assigned correctly to their true quarries of provenance leaving non-negligible possibilities of misclassification. However, if the database is more properly tailored, according to specific artifact properties, the rate of success increases considerably. In this way it can be shown that the subset of fine-grained marbles (7 groups, MGS \leq 1.0 mm) can be discriminated approximately at the 95% level. A second point to mention is the fact that individual provenances are based on probability parameters that allow us to distinguish reliable from uncertain assignments quite clearly. In the present case only very few provenances turned out to be statistically uncertain and always refer to the less used marbles. Probably the most problematic example is a portrait identified as Maximianus Herculeus now in the Museum of Fine Arts at Boston (inv. 61.1136). Although statistical analysis indicates that Hymettian marble was used, the probability values are low and this could be, in fact, another Göktepe marble artifact.

None of the assignments involving the four main marbles mentioned above seem to be questionable and

this is clearly demonstrated by the multi analytical graph of Figure 2 that shows that the fields of Göktepe, *Lychnites*, Carrara and Docimium are almost completely separated and allow easy and safe assignments.

4.2. Selected provenance results

Among the many examples that can be mentioned the four portraits of Trajan from the Roman villa of Chiragan shown in Figure 3 are especially important because they represent the earliest use of white Göktepe marble identified for Imperial portraits. Figure 4a shows that samples Ra58b and Ra58c are clear examples of Göktepe marble, whereas Ra58a and Ra117 were made using *lychnites* and Luna marble, respectively. Before Trajanic times no example of a Göktepe portrait could be found. The isotopic graph of Figure 4b shows that *lychnites* was the marble of choice in the Julio-Claudian period, whereas Carrara apparently took the lead in Flavian times. As already noted, however, the nine Flavian portraits tested are too few to obtain conclusive evidence; in addition, none of three marbles identified in this period shows a clear primacy.

A sharp change occurred at the beginning of the 2nd century AD when the use of Göktepe marble grew substantially. Obviously the use of other varieties did not disappear but Göktepe became by far the most sought after marble used for sculpture. The famous portrait of Hadrian discovered near the Stazione Termini and now at Palazzo Massimo (inv. 124491), the beautiful posthumous portrait of Trajan in the Museum of Ostia (Fig. 5), the portraits of young Hadrian and Sabine in Hadrian's Villa, two portraits of Lucius Verus (inv. 1131 and 1170) and one of Marcus Aurelius (inv. 1179) found in the villa at Acqua Traversa and now at the Louvre, as well as many

Fig. 3. The four Chiragan Trajan's portraits tested at Toulouse. Ra58b (a) and Ra58c (b) are Göktepe marble; Ra 58a (c) is lychnites and Ra117 (d) is Luna marble from Carrara

other examples are all made using the white marble of Göktepe, whereas a fourth portrait of Lucius Verus also in the Louvre (inv. 1094) proved to be Docimium marble from Iscehisar (Fig. 4c). Additional famous Antonine artifacts are the portrait of Commodus as Herakles in the Capitoline Museums (inv.1120) and the beautiful Getty Museum portrait of Commodus, whose authenticity is still controversial. The two sculptures shown in Figure 6 and commonly considered to be of Carrara marble, are, in fact, further examples of Göktepe marble as clearly shown by the graph of Figure 4c.

The most striking results, however, were obtained analyzing Severan portraits. Ten portraits of Caracalla were tested: nine of them proved to be Göktepe, whereas the last one (Capitoline Museums, inv. 468) is made of the marble from the so-called urban quarries of Aphrodisias (Fig. 4d).¹¹ All in all, 30 Severan portraits were tested and

24 of them, that is 80%, turned out to be Göktepe marble. During the late Empire the trend did not change. Ten of the 18 portraits tested (55.6%) proved to be Göktepe and the percent rises to 71% if the four Chiragan portraits tested in Toulouse and known as the dynastic group are neglected. They are late provincial artifacts that were manufactured using the local St. Béat marble. Figure 4e illustrates the Göktepe provenance of the two latest sculptures: the portraits of Valens in the Uffizi (inv. 273) and in the Capitoline (inv. 494). This latter, in fact, can be even later if the identification as Honorius is accepted.

Beyond the exact number of Göktepe artifacts identified and the diachronic information that they imply, the aim of this brief overview was that of demonstrating the widespread use of Göktepe and the clear evidence with which it can be identified, if proper analyses are carried out. In the past, most of the Göktepe sculptures mentioned above were considered to be Carrara, owing to the fact that the two marbles are very similar not only macroscopically, but also petrographically and

11 In general such homogeneous use of marble for the portraits of a single Emperor is not the rule. For instance five different marbles were identified for the 13 portraits of Antoninus Pius: Göktepe (7), *Lychnites* (2), Carrara

(2), Docimium (1), Thasian dolomite (1).

Fig. 4. Provenance of selected artifacts: (a) four Chiragan Trajan's portraits made of Göktepe, lychnites and Carrara marble; (b) overall isotopic graph of 28 Julio-Claudian and 9 Flavian portraits showing the widespread use of lychnites in the 1st century AD; (c) selected Hadrianic and Antonine portraits mostly made of Göktepe marble; (d) ten portraits of Caracalla nine of which are Göktepe and one marble from the Aphrodisias city quarries; (e) portraits of Valens in the Uffizi and Valens or perhaps Honorius in the Capitoline Museums both made of Göktepe marble. These are the latest artifacts tested

isotopically. However, they differ completely in terms of trace composition. The problem of Carrara/Göktepe discrimination is discussed in detail in another paper in this volume¹² and is based on the very high strontium content and very low concentration of manganese typical of the latter, which unmistakably mark the provenance and allow easy and unquestionable identification.

4.3. Overall distribution and diachronic data

The provenance results obtained in this study deliver important diachronic information, illustrated by the graphs of Figures 7 and 8, which can be summarized as follows:

- Use of the marble of Göktepe for fine portrait sculpture and in particular Imperial portraits started at the turn of the 1st and 2nd centuries, at the time of Trajan and rapidly spread and became dominant under the reign of Hadrian. The trend continued till late antiquity with percentages that,

12 PROCHASKA, ATTANASIO, BRUNO in this volume.

Fig. 8. Scatterplot illustrating diachronically use of the four most important marble varieties employed for Imperial portraiture

using the present data set, rise to 80% in Severan times and never go below the 53% value measured for the late Antonine period.

- Correspondingly the use of other marbles changed substantially. The Parian *lychnites* that till the mid-first century AD were the marble of choice for this type of sculpture (75%) underwent a strong decrease in later periods almost disappearing from the late 2nd century onwards.
- The case of Carrara is different. Apart from a slightly decreasing trend that is visible but not fully clear, the novel result is that the role of this marble seems to be greatly reduced with respect to previous results. The reason is that in the past most Göktepe portraits were misclassified as Carrara on the basis of visual inspection or incomplete or unsuitable analyses.
- The use of Docimium is also limited and seems to be restricted to Antonine and Severan times when a wider suite of different marbles was used.
- The presence of other marbles is quite limited and becomes significant only if they are considered as a whole (15%).
- Higher values were obtained only in Flavian (33%) and Later Empire times (39%). The former result is due to the popularity that Pentelicon marble enjoyed in the late 1st century AD, suggesting that in this case it should be added to the list of the most important marbles. At variance with this, the 39% value measured for the Late Empire is strongly biased by the analyses of four provincial Chiragan portraits, the “dynastic group” already mentioned, that were made using the local St. Béat marble.

Of course the present data selection is in many ways limited and preliminary. As compared to the total number of surviving portraits, only a tiny fraction was analyzed and it largely reflects the marble use that was trendy in the Imperial capital, whereas comparable studies carried out in provincial contexts have been deferred. Despite this, there are two main reasons that support, to some extent, the general value of the results. The first is that the sculptures were selected entirely by chance and therefore are considered to represent a relatively unbiased set, reproducing fairly well the actual distribution of Imperial portrait marbles. Secondly the change in the marble used, particularly the replacement of *lychnites* by Göktepe, appears to be sharp and pervasive to such an extent that it can hardly be substantially modified by increasing the number of portraits tested in Rome.

5. Conclusions

The extraordinary success met by the marble of Göktepe as the material of choice for high quality sculptures including Imperial but also private portraits and ideal sculpture poses a number of problems involving the reasons for this success and the influence that it may have exerted on the sculptural styles that became fashionable in the second century and later. Obviously no conclusive answers can be given here and much more work will certainly be needed to obtain a satisfactory solution. Nevertheless certain questions can be posed and some preliminary and tentative explanations can be attempted.

The decreased use of Parian *lychnites* and the search for alternative sources of fine quality marble may have been fostered by the depletion of Parian quarries that were not able anymore to produce the amount of the best quality varieties that were needed. There are no

quantitative data on this possibility, however, and it must be recalled that the use of *lychnites* continued well into the third century and later, though on a much reduced scale. The Göktepe alternative however, is not immediately obvious: the site is rather small and unfavourably located with the consequence that the production was relatively limited and stone transport difficult and expensive. The excellent quality of the marble, of course, is important and certainly played a key role; still it does not seem to be able by itself to explain the extraordinary success met by this variety. Several alternatives existed and Göktepe does not seem to be so much superior in appearance or carving properties to the best qualities of Docimium or Luna marble. In conclusion it may be argued that the crucial point was the tight connection existing between Göktepe and the Aphrodisian craftsmen who promoted its use and were the most prominent sculptors of their time owing to the stylistic and technical novelties that they introduced. Their signatures, which explicitly mention the ethnicity of the artist, and the marble, that comes predominantly from Göktepe or sometimes from the city quarries of Aphrodisias, were used apparently to certify the Aphrodisian workmanship and to act in some way as a mark of origin.

The Göktepe-Aphrodisias association, however, refers mostly to the introduction and early use of the marble. Later on, the sculptural use of Göktepe became pervasive, implying that it was adopted by the most renowned sculptural ateliers in Rome whether or not they had Aphrodisian origin or connections. Following a reasoning that is certainly hypothetical but also likely and to some extent inescapable it must be admitted that it would be difficult to assume that the urban ateliers borrowed from Aphrodisians only the marble without adopting, at least partly, the technical and stylistic peculiarities that fostered their fame. To conclude it may be stated that marble studies seem to emphasize the role played by the Aphrodisian sculptors in determining the stylistic trends that developed in Rome during the Imperial period, providing a crucial contribution to what is commonly called the urban style of sculpture.
